

Page 1: Digital Overview

This is selectable digital text on the first page of the mixed document. Modern distributed systems rely on containerization, orchestration, and automated scaling to handle dynamic workloads.

Page 2: Storage Architecture

Storage subsystems utilize block, file, and object interfaces to satisfy varying latency and throughput requirements. Solid state drives and non-volatile memory provide microsecond access times.

Page 3: Visual Topology

Digital text on page 3 accompanying a system topology diagram. Network latency and bandwidth determine the optimal partitioning strategy across clusters.

Figure 1: System Topology Overview

Page 4: Performance Monitoring

Performance monitoring continuously tracks CPU utilization, memory allocation, network throughput, and garbage collection pauses across all nodes.
